<sup>(a)</sup> Basado en los criterios definidos en Golder (2007): Proyecto Petaquilla – Revisión de la calidad del agua de parte de los reguladores.

<sup>(b)</sup> En los cálculos estadísticos se utilizó un valor de la mitad del límite de detección.

<sup>(c)</sup> P: Reglamento panameño 351 Concentraciones máximas permisibles en el agua potable (1999);

AO: Objetivo estético

0.3 - denota una excedencia por encima de los criterios seleccionados asociados a la Salud Humana.

CCME: Consejo Canadiense de Ministros del Medio Ambiente, Lineamientos Canadienses para la Salud Humana para la Calidad del Agua Potable en Canadá (2008);

ORNL: Niveles de análisis del agua del grifo del Oak Ridge National Laboratory para contaminantes químicos en sitios del Superfondo (lineamientos ajustados para reflejar un ILCR de 10-5, HQ de 0.2) (Septiembre 2008).

<sup>(a)</sup> Basado en los criterios definidos en Golder (2007): Proyecto Petaquilla - Revisión de la calidad del agua de parte de los reguladores.

<sup>(b)</sup> En los cálculos estadísticos, se utilizó un valor de la mitad del límite de detección.

<sup>(c)</sup> P: Reglamento panameño 351 Concentraciones máximas permisibles en el agua potable (1999);AO: Objetivo estético

**0.3** - denota una excedencia por encima de los criterios seleccionados asociados a la Salud Humana.

CCME: Consejo Canadiense de Ministros del Medio Ambiente, Health Canada Guidelines for Canadian Drinking Water Quality (2008);

ORNL: Niveles de análisis del agua del grifo del Oak Ridge National Laboratory para contaminantes químicos en sitios del Superfondo (lineamientos ajustados para reflejar un ILCR de 10-5, HQ de 0.2) (Septiembre 2008).

Tabla 14      Tabla de Análisis de Calidad de Agua Potable de Línea Base para la Evaluación de Riesgos a la Salud Humana y a la Ecología

<sup>(a)</sup> Basado en los criterios definidos en Golder (2007): Proyecto Petaquilla - Revisión de la calidad del agua de parte de los reguladores.

<sup>(b)</sup> En los cálculos estadísticos, se utilizó un valor de la mitad del límite de detección.

0.3 - denota una excedencia por encima de los criterios seleccionados asociados a la salud

<sup>(a)</sup> Basado en los criterios definidos en Golder (2007): Proyecto Petaquilla - Revisión de la calidad del agua de parte de los reguladores.

<sup>(b)</sup> En los cálculos estadísticos, se utilizó un valor de la mitad del límite de detección.

**0.3** - denota una excedencia por encima de los criterios seleccionados asociados a la salud.

Tabla 16 Tabla de Análisis de Calidad de Agua Dulce de Línea Base para la Evaluación de Riesgos a la Salud Ecológica (Cuenca del Río Petaquilla)

<sup>(a)</sup> Basado en los criterios definidos en Golder (2007): Proyecto Petaquilla - Revisión de la calidad del agua de parte de los reguladores.

<sup>(b)</sup> En los cálculos estadísticos, se utilizó un valor de la mitad del límite de detección.

**0.3** - denota una excedencia por encima de los criterios seleccionados asociados a la salud.

<sup>(a)</sup> Basado en los criterios definidos en Golder (2007): Proyecto Petaquilla - Revisión de la calidad del agua de parte de los reguladores.

<sup>(b)</sup> En los cálculos estadísticos, se utilizó un valor de la mitad del límite de detección.

**0.3** - denota una excedencia por encima de los criterios seleccionados asociados a la salud.

<sup>(a)</sup> Basado en los criterios definidos en Golder (2007): Proyecto Petaquilla - Revisión de la calidad del agua de parte de los reguladores.

<sup>(b)</sup> En los cálculos estadísticos, se utilizó un valor de la mitad del límite de detección.

**0.3** - denota una excedencia por encima de los criterios seleccionados asociados a la salud humana.

(a) Niveles de análisis para peces en base al riesgo para peces en la región 3 de la APAEU (Mayo 2008); Normas específicas del sitio: m = metálico; d = dieta; p = partículas de cromo VI; i = sales inorgánicas; s = sales solubles; h = metilmercurio.

Nota: Todas las unidades están en miligramos por kilogramo, peso húmedo (mg/kg, de peso húmedo), salvo que se haya indicado de otro modo; < = menos la concentración detectable mínima.

|            |                                                                                    |
|------------|------------------------------------------------------------------------------------|
| <u>500</u> | Igual o mayor al nivel de análisis en base al riesgo.                              |
| 500        | El límite de detección del método es mayor al nivel de análisis en base al riesgo. |

(a) Niveles de análisis para peces en base al riesgo para peces en la región 3 de la APAEU (Mayo 2008); Normas específicas del sitio: m = metálico; d = dieta; p = partículas de cromo VI; i = sales inorgánicas; s = sales solubles; h = metilmercurio.

Nota: Todas las unidades están en miligramos por kilogramo, peso húmedo (mg/kg, de peso húmedo), salvo que se haya indicado de otro modo; < = menos la concentración detectable mínima.

(a) Niveles de análisis para peces en base al riesgo para peces en la región 3 de la APAEU (Mayo 2008).  
Nota: Todas las unidades están en miligramos por kilogramo, peso húmedo (mg/kg, de peso húmedo), salvo que se haya indicado de otro modo; < = menos la concentración detectable mínima.

|     |                                                                                   |
|-----|-----------------------------------------------------------------------------------|
| 500 | Igual o mayor al nivel de análisis en base al riesgo                              |
| 500 | El límite de detección del método es mayor al nivel de análisis en base al riesgo |

(a)      Niveles de análisis para peces en base al riesgo para peces en la región 3 de la APAEU (Mayo 2008).  
Nota:    Todas las unidades están en miligramos por kilogramo, peso húmedo (mg/kg, de peso húmedo), salvo que se haya indicado de otro modo; < = menos la concentración detectable mínima.

|            |                                                                                    |
|------------|------------------------------------------------------------------------------------|
| <u>500</u> | Igual o mayor al nivel de análisis en base al riesgo.                              |
| 500        | El límite de detección del método es mayor al nivel de análisis en base al riesgo. |

**Tabla 30      Resumen de las Concentraciones de Metales en el Aire - Línea Base**

| <b>Ubicación<br/>Parámetro</b> | <b>Río Caimito</b> | <b>Nueva Lucha</b> | <b>Nuevo Sinai</b> | <b>San Benito</b> |
|--------------------------------|--------------------|--------------------|--------------------|-------------------|
| aluminio                       | 3.00E-02           | 3.98E-02           | 4.64E-02           | 2.63E-02          |

(a) Niveles de análisis para peces en base al riesgo para peces en la región 3 de la APAEU (Mayo 2008); Normas específicas del sitio: m = metálico; d = dieta; p = partículas de cromo VI; i = sales inorgánicas; s = sales solubles; h = metilmercurio.

Nota: Todas las unidades están en miligramos por kilogramo, peso húmedo (mg/kg, de peso húmedo), salvo que se haya indicado de otro modo; < = menos la concentración detectable mínima.

|     |                                                |
|-----|------------------------------------------------|
| 0.3 | Excede la norma para tejido muscular de peces. |
| 0.3 | Coefficiente de aumento > 1.1.                 |

(a) Consejo Canadiense de Ministros del Medio Ambiente (CCME 2008); Lineamientos Canadienses de Calidad de Suelos para la Protección de Medio Ambiente y la Salud Humana; Los factores específicos del sitio incluyen: i= ingestión de suelo; c = contacto con el suelo; n = ínterin; d = contacto directo; p = provisional.

(b) En caso que una norma del CCME aplicable no estuviera disponible, se utilizaron, se utilizaron los niveles de análisis de suelo residencial regional para contaminantes químicos en el sitio del Superfondo del Oakridge National Laboratory (Set. 2008) (lineamientos ajustados para reflejar un ILCR de 10<sup>-5</sup>, HQ de 0.2)

(c) Se brindan lineamientos para uso de tierras residenciales (RL) y uso de tierras agrícolas (AL) cuando están disponibles

(d) Un parámetro es considerado como COPC si excede el lineamiento mínimo y la concentración en caso de impacto fue mayor que la concentración de línea base en más de 10%.

(e). Ninguna concentración de fondo está disponible; el COPC será evaluado como parte del total de Cromo

(f) Ninguna norma está disponible; la concentración máxima fue más baja que el criterio mínimo de HAP (es decir, 1 mg/kg); COPC - Contaminante de Interés Potencial

(e) Nivel de análisis regional del APAEU (carcinógenos ajustados para un riesgo de cáncer de 10<sup>-5</sup> y no carcinógenos ajustados para justificar los mecanismos de exposición adicionales (\*0.2)); \* B[a]P TPE – Equivalentes de Potencia Total es la suma de la potencia de cáncer calculada en relación con un B[a]P usando los siguientes factores de equivalencia: benzo(a)antraceno = 0.1, benzo(a)pireno = 1; benzo(b)fluoranteno = 0.1; benzo(k)fluoranteno = 0.1; criseno = 0.01; benzo(g,h,i)perileno = 0.01; dibenzo(a,h)antraceno = 1; indeno(1,2,3-c,d)pireno = 0.1. En el caso en que no se ha detectado un parámetro, se utilizó la mitad del límite de detección.

Nota: Todas las unidades están en miligramos por kilogramo, peso húmedo (mg/kg, de peso húmedo), salvo que se haya indicado de otro modo; < = menos la concentración detectable mínima; ND – No disponible; NM – No medido.

(a) Consejo Canadiense de Ministros del Medio Ambiente (CCME 2008); Lineamientos Canadienses de Calidad de Suelos para la Protección de Medio Ambiente y la Salud Humana.

(b) Los factores específicos del sitio incluyen: i= ingestión de suelo; c = contacto con el suelo; n = ínterin; d = contacto directo; p = provisional.

(c) Se brindan lineamientos para uso de tierras residenciales (RL) y uso de tierras agrícolas (AL) cuando están disponibles.

(d) Un parámetro es considerado como COPC si excede el lineamiento mínimo y la concentración en caso de impacto fue mayor que la concentración de línea base en más de 10%.

(e) Ninguna norma ni ninguna concentración de fondo están disponibles; se considera como COPC porque se consideró el total de Cromo (será evaluado como total de Cromo).

(f) Los HAP sin criterios de análisis fueron analizados de manera conservadora comparados con el criterio para benzo(a)pireno (es decir, 0.6 mg/kg).

(g) Ninguna norma ni ninguna concentración de fondo están disponibles; consideradas porque la concentración prevista fue de >10% desde la línea base.

Nota: Todas las unidades están en miligramos por kilogramo; peso húmedo (mg/kg, de peso húmedo) salvo que se haya indicado de otro modo; < = menos la concentración detectable mínima; COPC - Contaminante de Interés Potencial; ND – No disponible; NM – No medido, n/a = ningún criterio de análisis o dato de línea base está disponible.

# 1 EVALUACIÓN DEL EFECTO DE LA EXPOSICIÓN A LA SALUD HUMANA

## 1.1 EVALUACIÓN DE LA EXPOSICIÓN

La evaluación de la exposición consiste de una serie de ecuaciones con el fin de calcular la tasa de absorción química diaria promedio, normalizada al peso corporal (es decir dosis de exposición) para cada combinación CIP-medio-receptor. A continuación se presenta la ecuación utilizada para estimar las dosis de exposición (Health Canada 2007) y las dosis de exposición calculadas:

**Nivel de dosis de ingesta de agua potable contaminada:**

|        |                                                                 |            |
|--------|-----------------------------------------------------------------|------------|
| DRDW = | $CW \times TIA \times FAR_{oral} \times D2 \times D3 \times D4$ | Ecuación 1 |
|        | $PC \times EV$                                                  |            |

donde:

DRDW = nivel de dosis a partir de la ingesta de CIP en el agua potable (mg/kg peso corporal-día)

TIA = tasa de ingesta de agua (L/d)

Cw = concentración de CIP en agua subterránea (mg/L)

FAR<sub>oral</sub> = factor de absorción relativa del tracto gastrointestinal (sin unidad) - se asumió conservadoramente a los RAF como 1

D2 = días de exposición por semana / 7 días

D3 = semanas de exposición por año / 52 semanas

D4 = total de años de exposición del área (sólo para cancerígenos)

PC = peso corporal (kg)

EV = expectativa de vida (años) (sólo para cancerígenos)

**Nivel de dosis de ingesta de alimentos (utilizado para peces, fruta, arroz, carne de vacuno y pollo):**

|       |                                                           |            |
|-------|-----------------------------------------------------------|------------|
| DRF = | $IR\ F \times CF \times FF \times D1 \times D2 \times D3$ | Ecuación 2 |
|       | $PC \times EV$                                            |            |

donde:

DRF = nivel de dosis a partir de la ingesta de CIP en los alimentos (mg/kg peso corporal/día)

TIA = tasa de ingesta de alimentos (kg/día)

CF = Concentración de CIP en alimentos (mg/kg)

FF = fracción de un alimento de la dieta obtenida del área (sin unidad)

D1 = días de exposición por semana / 7 días

D2 = semanas de exposición por año / 52 semanas

D3 = total de años de exposición del área (sólo para cancerígenos)

PC = peso corporal (kg)

EV = expectativa de vida (años) (sólo para cancerígenos)

**Nivel de dosis de ingesta inadvertida de suelos:**

|        |                                                                   |            |
|--------|-------------------------------------------------------------------|------------|
| DRS/TI | $IR\ S/TI \times CS/T \times AF\ S \times D1 \times D2 \times D3$ | Ecuación 3 |
|        | $PC \times EV$                                                    |            |

donde:

DRS = dosis estimada a partir de la ingesta de CIP en los sedimentos (mg/kg peso corporal/día)

IRS = tasa de ingesta de sedimentos (kg/día)

CS = concentración de CIP en los sedimentos (mg/kg)

AFS = factor de biodisponibilidad a través de la ingesta de sedimentos (sin unidad) – se asumió conservadoramente como 1 para esta evaluación de riesgos

D1 = días de exposición por semana / 7 días

D2 = semanas de exposición por año / 52 semanas

D3 = total de años de exposición del área (sólo para cancerígenos)

PC = peso corporal (kg)

EV = expectativa de vida (años) (sólo para cancerígenos)

### Contacto dérmico con los sedimentos:

|        |                                            |            |
|--------|--------------------------------------------|------------|
| DRDC = | CS/T x SA x AD x AFDC x UCF x D1 x D2 x D3 | Ecuación 4 |
|        | PC x EV                                    |            |

donde:

DRDC = nivel de dosis a partir del contacto dérmico con CIP en los sedimentos (mg/kg peso corporal-día)

SA = área de superficie cutánea disponible para el contacto dérmico (cm<sup>2</sup>/evento)

AD = factor de adherencia (suelo a piel; mg/cm<sup>2</sup>)

CS = concentración de CIP en los sedimentos (mg/kg)

AFDC = biodisponibilidad a través del contacto dérmico (sin unidad) – se asumió conservadoramente como 1 para esta evaluación de riesgos

UCF = factor de conversión de unidades (1 x 10<sup>-6</sup> kg/mg)

D1 = días de exposición por semana / 7 días

D2 = semanas de exposición por año / 52 semanas

D3 = total de años de exposición del área (sólo para cancerígenos)

PC = peso corporal (kg)

EV = expectativa de vida (años) (sólo para cancerígenos)

### Ingesta inadvertida de agua superficial:

|        |                                   |            |
|--------|-----------------------------------|------------|
| DRSI = | TIAS x CDW x AFGIT x D1 x D2 x D3 | Ecuación 5 |
|        | PC x EV                           |            |

Donde:

DRDW = nivel de dosis a partir de la ingesta de CIP en el agua superficial (mg/kg peso corporal/día)

TIAS = tasa de ingesta de agua superficial (L/día)

CS = concentración de CIP en agua potable (mg/L)

AFGIT = factor de biodisponibilidad a través del tracto gastrointestinal

D1 = días de exposición por semana / 7 días

D2 = semanas de exposición por año / 52 semanas

D3 = total de años de exposición del área (sólo para cancerígenos)

PC = peso corporal (kg)

EV = expectativa de vida (años) (sólo para cancerígenos)

### Contacto dérmico con el agua superficial para sustancias orgánicas:

|        |                               |            |
|--------|-------------------------------|------------|
| DRDC = | SA x DA evento x D1 x D2 x D3 | Ecuación 6 |
|        | PC x EV                       |            |

donde:

DRDC = nivel de dosis a partir del contacto dérmico con CIP en agua superficial (mg/kg peso corporal-día)

SA = área de superficie cutánea disponible para el contacto dérmico (cm<sup>2</sup>)

Evento DA = dosis absorbida por evento (mg/cm<sup>2</sup>-evento) (las ecuaciones se describen más adelante)

D1 = días de exposición por semana / 7 días

D2 = semanas de exposición por año / 52 semanas

D3 = total de años de exposición del área (sólo para cancerígenos)

PC = peso corporal (kg)

EV = expectativa de vida (años) (sólo para cancerígenos)

### Nivel de dosis de ingesta inadvertida de suelos:

|        |                                               |            |
|--------|-----------------------------------------------|------------|
| DRSI = | CS x IRS x RAF <sub>Oral</sub> x D1 x D2 x D3 | Ecuación 7 |
|        | PC x EV                                       |            |

donde:

DRI = dosis estimada a partir de la ingesta de CIP en el suelos (mg/kg peso corporal-día)

IRS = tasa de ingesta de sedimentos (kg/día)

CS = concentración de CIP en el suelo (mg/kg)

FA<sub>Roral</sub> = biodisponibilidad a través de la ingesta de suelo, es decir, factor de absorción relativa del tracto gastrointestinal (sin unidad)

D1 = días de exposición por semana / 7 días

D2 = semanas de exposición por año / 52 semanas

D3 = total de años de exposición del área (sólo para cancerígenos)

PC = peso corporal (kg)

EV = expectativa de vida (años) (sólo para cancerígenos)

### Nivel de dosis de contacto dérmico con el suelo:

|        |                                                                                                                                            |            |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------|------------|
| DRDC = | $\frac{[(CS \times SAH \times SLH) + (CS \times SAO \times SLO)] \times RAF_{\text{dérmica}} \times D1 \times D2 \times D3}{PC \times EV}$ | Ecuación 8 |
|        |                                                                                                                                            |            |

donde:

DRDC = nivel de dosis a partir del contacto dérmico con CIP en el suelo (mg/kg peso corporal-día)

SAH = área de superficie cutánea disponible para el contacto dérmico (manos) (cm<sup>2</sup>)

SLH = carga de suelo para la piel expuesta (manos) (kg/m<sup>2</sup>-día)

SAO = área de superficie cutánea disponible para el contacto dérmico (áreas distintas de las manos) (m<sup>2</sup>)

SLO = carga de suelo para la piel expuesta (áreas distintas de las manos) (kg/m<sup>2</sup>-día)

CS = concentración de CIP en el suelo (mg/kg)

RAFDC = biodisponibilidad a través del contacto dérmico (sin unidad)

D1 = días de exposición por semana / 7 días

D2 = semanas de exposición por año / 52 semanas

D3 = total de años de exposición del área (sólo para cancerígenos)

PC = peso corporal (kg)

EV = expectativa de vida (años) (sólo para cancerígenos)

### Nivel de dosis de inhalación de partículas de suelo contaminadas:

|        |                                                                                              |            |
|--------|----------------------------------------------------------------------------------------------|------------|
| DRIH = | $Cs \times IRA \times Paire \times RAF_{\text{inh}} \times D1 \times D2 \times D3 \times D4$ | Ecuación 9 |
|        | $PC \times EV$                                                                               |            |

donde:

DRIH = nivel de dosis a partir de la inhalación de CIP en las partículas transportadas por el aire (mg/kg peso corporal-día)

IRA = tasa de inhalación del receptor (m<sup>3</sup>/hora)

CS = concentración de CIP en el suelo (mg/kg)

Paire = concentración de material particulado en el aire (kg/m<sup>3</sup>)

RAF<sub>inh</sub> = biodisponibilidad a través de la inhalación (sin unidad)

D1 = horas de exposición por día (horas/día)

D2 = días de exposición por semana / 7 días

D3 = semanas de exposición por año / 52 semanas

D4 = total de años de exposición del área (sólo para cancerígenos)

PC = peso corporal (kg)

EV = expectativa de vida (años) (sólo para cancerígenos)

### Nivel de dosis de inhalación de aire contaminante:

|       |                        |             |
|-------|------------------------|-------------|
| DRV = | CA x D1 x D2 x D3 x D4 | Ecuación 10 |
|       | EV                     |             |

donde:

DRV = nivel de dosis a partir de la inhalación de CIP en el aire ( $\text{mg}/\text{m}^3$ )

CS = concentración de CIP en el aire ( $\text{mg}/\text{m}^3$ )

AFinh = biodisponibilidad vía inhalación (sin unidad) – se asumió conservadoramente como 1

D1 = horas de exposición por día /24 horas)

D2 = días de exposición por semana / 7 días

D3 = semanas de exposición por año / 52 semanas

D4 = total de años de exposición del área (sólo para cancerígenos)

PC = peso corporal (kg)

EV = expectativa de vida (años) (sólo para cancerígenos)

### 1.1.1 Cálculo de la dosis dérmica absorbida por el contacto con el agua superficial

El método para calcular la dosis dérmica absorbida es el recomendado por USEPA (2004), la absorción dérmica se basa en un modelo de dos compartimentos el cual consta de dos capas: el estrato o capa córnea y la epidermis viable. El modelo describe la absorción de CIP del agua a través de la piel como una función del estrato o capa córnea y la duración del evento (USEPA 2004), dicho estrato o capa córnea funciona como la barrera principal para los CIP. Las siguientes ecuaciones se utilizan para calcular la dosis absorbida por la piel para CIP inorgánicos.

### Dosis absorbida por la piel (evento DA) para sustancias inorgánicas en agua superficial:

|           |                                           |             |
|-----------|-------------------------------------------|-------------|
| DAevento= | $K_p \times C_w \times t_{\text{evento}}$ | Ecuación 11 |
|-----------|-------------------------------------------|-------------|

donde:

DAevento = dosis absorbida por evento ( $\text{mg}/\text{cm}^2\text{-evento}$ )

FA = agua absorbida por la fracción (sin unidad)

$K_p$  = coeficiente de permeabilidad dérmica del compuesto en el agua ( $\text{cm}/\text{hora}$ ), específico por químico y obtenido de USEPA (2004a)

$C_w$  = concentración de químicos en el agua ( $\text{mg}/\text{cm}^3$ )

### **1.1.2 Parámetros de exposición**

A continuación en la Tabla 1 se presenta los parámetros de exposición de los receptores utilizados en los cálculos. Cuando no se dispuso de información específica para el área, se utilizó los valores estándar basados en fuentes publicadas (USEPA 1997, Health Canada 2007).

La información específica para el área relativa a la frecuencia de la ingesta de alimentos y actividades se obtuvo mediante entrevistas efectuadas por el Equipo Socioeconómico (Apéndice XX). Se recabó información semicuantitativa limitada con respecto a las porciones de alimentos consumidos y se complementó con información de un estudio en los patrones de estado nutricional y consumo de alimentos en Panamá (República de Panamá).

La información sobre el consumo de alimentos para varias comunidades dentro del área de estudio se presenta en las Tablas 2 a 9, la relativa a las comunidades costeras tomó como base la información del Río Caimito, en el caso de las comunidades agrícolas se tomó como base la información de San Benito, Coclesito y Los Molejones y finalmente para las comunidades indígenas, se tomó como base la información de Nuevo Sinaí y Nuevo Lucha. En la Tabla 10 se presenta las tasas de consumo de alimentos en la República de Panamá (2002, 2006).

Tabla 1 Características del Receptor y Parámetros de Exposición

| Parámetros                                                 | Niño de Comunidad Costera<br>(6 meses a 4 años) | Adulto de Comunidad Costera<br>(mayor de 20 años) | Niño de Comunidad Indígena<br>(6 meses a 4 años) | Adulto de Comunidad Indígena<br>(mayor de 20 años) | Niño de Comunidad Agrícola<br>(6 meses a 4 años) | Adulto de Comunidad Agrícola<br>(mayor de 20 años) | Niño de los Alrededores del Cerco Perimetral<br>(6 meses a 4 años) | Adulto de los Alrededores del Cerco Perimetral<br>(mayor de 20 años) |
|------------------------------------------------------------|-------------------------------------------------|---------------------------------------------------|--------------------------------------------------|----------------------------------------------------|--------------------------------------------------|----------------------------------------------------|--------------------------------------------------------------------|----------------------------------------------------------------------|
| peso corporal (kg)                                         | 16.5                                            | 70.7                                              | 16.5                                             | 70.7                                               | 16.5                                             | 70.7                                               | 16.5                                                               | 70.7                                                                 |
| Vías de Ingesta de Alimentos y Agua Potable:               |                                                 |                                                   |                                                  |                                                    |                                                  |                                                    |                                                                    |                                                                      |
| tasa de ingesta de agua potable (L/día) <sup>(a)</sup>     | 0.9                                             | 2.25                                              | 0.9                                              | 2.25                                               | 0.9                                              | 2.25                                               | NA                                                                 | NA                                                                   |
| días/año de exposición - agua potable                      | 365/365                                         | 365/365                                           | 365/365                                          | 365/365                                            | 365/365                                          | 365/365                                            | NA                                                                 | NA                                                                   |

# **1 EVALUACIÓN DE LA TOXICIDAD**

## **1.1 VALORES REFERENCIALES DE TOXICIDAD (VRT)**

La evaluación de toxicidad se realizó para todos los CIP e involucró la identificación de los posibles efectos tóxicos de los químicos y la selección de los valores referenciales de toxicidad (VRT) para cada uno de ellos. Los VRT incluyen dosis de referencia (DR) e ingestas diarias tolerables (mg/kg-día), (IDT) y concentraciones referenciales (CR) (mg/ m<sup>3</sup>) para agentes no cancerígenos y factores de potencia o pendiente de cáncer para agentes cancerígenos. Una dosis o concentración de referencia representa una ingesta diaria tolerable que receptores humanos pueden recibir cada día durante toda su vida sin experimentar ningún impacto significativo o negativo para la salud. Los factores de la pendiente se utilizan para calcular el riesgo cancerígeno y se definen como la probabilidad máxima plausible de que una persona desarrolle cáncer como resultado de la exposición durante toda su vida a un posible agente cancerígeno.

Se calcularon los valores de los cocientes de riesgo y de los riesgos incrementales de desarrollar cáncer de por vida (ILCR) para agentes cancerígenos, en lo posible.

Los valores de toxicidad utilizados en la evaluación de riesgos se obtuvieron principalmente de la Organización Mundial de la Salud (OMS 2000, 2008), el Sistema Integrado de Información de Riesgos de USEPA (USEPA IRIS 2009a) y *Health Canada* (Health Canada 2009). Cuando no se dispuso de valores referenciales de la OMS, USEPA IRIS o *Health Canada* para contaminantes de interés potencial, se utilizaron otras fuentes como valores referenciales de toxicidad provisionales revisados por expertos del Centro de Apoyo Técnico a Riesgos para la Salud del Centro Nacional para el Superfondo de Evaluación Ambiental (USEPA 2009c o RIVM 2001).

## **1.2 BIODISPONIBILIDAD**

La biodisponibilidad (también conocida como eficiencia de absorción) es una medida de la cantidad de un químico que se absorbe y retiene dentro del cuerpo. Pudiera ser importante considerar la biodisponibilidad en las siguientes circunstancias (USEPA 1989):

- si el medio de exposición es diferente al medio que se toma como base para el valor referencial de toxicidad (por ejemplo, la exposición proviene del suelo, aunque el valor referencial de toxicidad se basa en la exposición al agua);
- si la ruta de exposición es distinta a la ruta de exposición utilizada en el estudio con el fin de derivar el valor referencial de toxicidad (por ejemplo, ruta de exposición oral, aunque se basa en un estudio de inhalación); o

- el valor referencial de toxicidad derivado por la agencia de regulación se ajusta a la biodisponibilidad.

En la evaluación de la salud humana los estimados de exposición no se ajustan a la biodisponibilidad debido a que en la mayoría de los casos, los VRT se expresan como la dosis administrada (es decir, la cantidad que ingresó al cuerpo), en lugar de la dosis absorbida (es decir, la cantidad absorbida y retenida en el cuerpo) y no se dispone de información sobre la biodisponibilidad.

### ***Consideraciones Especiales – Arsénico en los Peces***

Se ha reportado que las formas de arsénico en peces y mariscos (es decir, arsenobetaina y arsenocolina) son esencialmente no tóxicas. Sin embargo un pequeño porcentaje en tejidos de los peces pudiera ser una forma inorgánica tóxica, por lo tanto se utiliza un contenido de 10% de arsénico inorgánico en los peces para calcular las exposiciones al arsénico a través de ellos (ATSDR 2005).

En el caso de la exposición dérmica se utilizaron los factores de absorción relativa proporcionados por *Health Canada* (2009). En ausencia de valores establecidos por *Health Canada* (2009), se seleccionaron factores de absorción relativa del Ministerio del Medio Ambiente de Ontario (2008).

## **1.3 CLASIFICACIÓN DE CONTAMINANTES**

Diversas organizaciones han desarrollado sistemas de clasificación basados en las propiedades cancerígenas de los químicos. En la Tabla 1 se presenta los sistemas de clasificación de la Agencia Internacional para la Investigación del Cáncer (IARC 2008), USEPA (2009a) y *Health Canada* (1996).

En la Sección 1.5 se consolidan los perfiles de toxicidad para todos los contaminantes de interés potencial, la farmacocinética de definición, la toxicidad, la clasificación de carcinogenicidad y los valores referenciales basados en la toxicidad, seleccionados con el fin de utilizarse en la evaluación de los riesgos para la salud humana. En la Tabla 3

se presenta un resumen de los valores referenciales de toxicidad seleccionados para la evaluación de riesgos.

Tabla 3 VRT Seleccionados para la Evaluación de los Riesgos para la Salud Humana

- (a) Las clasificaciones de *Health Canada* se obtienen de *Health Canada* 2008<sup>a</sup>, las clasificaciones USEPA se obtienen de USEPA IRIS (2009a).
- (b) El níquel metálico se clasifica en el grupo VI, el óxido de níquel, níquel soluble y sulfuro de níquel se clasifican en el grupo I.
- (c) VRT oral adoptado como VRT dérmico no disponible.
- (d) Níquel soluble utilizado para evaluar los efectos no cancerígenos (IDT mayoritariamente conservadoras), polvo de fundición de níquel utilizado con el fin de evaluar los efectos cancerígenos para la trayectoria de inhalación (es decir factor de pendiente).
- (e) DR para el vanadio basada en USEPA IRIS, DR para el pentóxido de vanadio con un ajuste del peso molecular (USEPA 2009c).
- (f) Factores de absorción dérmica relativa (FAR) se obtienen de *Health Canada* (2009).
- (g) USEPA IRIS clasifica al subsulfuro de níquel y al polvo de fundiciones de níquel en el grupo A y al carbonilo de níquel en el grupo B2. Las sales solubles de níquel como compuesto no se han clasificado.
- (h) CR por inhalación para particulados.

Notas: FP – factor de pendiente; DR – dosis referencial; CR – concentración referencial; FAR – factor de absorción relativa; HC - *Health Canada*; CCME – Consejo Canadiense de Ministros de Medio Ambiente; USEPA – Agencia para la protección de medio ambiente de los Estados Unidos; IRIS – Sistema Integrado de Información de Riegos; RAIS – Sistema de Información para la Evaluación de Riesgos (2009); OMS – Organización Mundial de la Salud; Tablas MPR – metas preliminares de remediación para la Región 9 de USEPA; valores de toxicidad provisionales revisados por expertos – EPA PPRTV; Centro Nacional para la Evaluación del Medio Ambiente – USEPA NCEA; DR se expresa en mg/kg-d; FP se expresa en (mg/kg-d)<sup>-1</sup>; CR se expresa en mg/m<sup>3</sup>; los riesgos unitarios se expresan en (mg/m<sup>3</sup>)<sup>-1</sup>; N/A = no aplicable.

## 1.4 EXPLORACIÓN DE LOS VALORES DE TOXICIDAD POR RUTA

La toxicidad de una sustancia se puede diferenciar por las rutas de exposición (por ejemplo oral frente a inhalación) y en consecuencia no se realizó una exploración de los CIP por ruta en ausencia de valores referenciales específicos para la inhalación (USEPA 2009b). Los valores de la DR por vía oral y los factores de la pendiente se utilizaron en forma conservadora con el fin de evaluar la exposición dérmica.

## 1.6 PERFILES DE TOXICIDAD

### *Aluminio*

#### **Farmacocinética**

En general la absorción del aluminio en seres humanos y animales es baja mediante vías de exposición oral e inhalación, la absorción dérmica es incluso menos significativa (ATSDR 2008).

#### Exposición Oral

Se estima que la absorción del aluminio a través de ingestas alimenticias normales es de 0.1% y se puede absorber en mayor cantidad si se trata de formas más biodisponibles (por ejemplo complejos con algunos ácidos carboxílicos) con una tasa más cercana al 1.0%. Las condiciones acuosas y el pH de los intestinos afectan la absorción (ATSDR 2008). Se ha demostrado que la distribución del aluminio después de una exposición oral en animales ocurre en el cerebro (hipocampo), también se ha encontrado que la ingesta concomitante de vitamina D mejora la acumulación y la retención de aluminio en los huesos, riñones, músculos y corazón (ATSDR 2008). La eliminación de aluminio después de la absorción oral en seres humanos y animales ocurre en los riñones (a través de la orina) y el no absorbido se excreta principalmente a través de las heces. En un estudio con ratas se encontró que una dosis oral única de 11 mg aumenta 14 veces los niveles de aluminio en la orina dentro de las siguientes 24 horas posteriores a la exposición y que los niveles vuelven a la normalidad después de 5 días (ATSDR 2008).

#### Exposición por Inhalación

Los estudios sobre exposición por inhalación realizados en seres humanos descubrieron que la exposición ocupacional a vapores de aluminio, polvo y escamillas aumenta los niveles séricos y que la absorción directa en el cerebro pudiera ocurrir a través del tracto olfativo mediante el transporte axónico. En los resultados arrojados por la autopsia realizada a un picapedrero expuesto a aluminio se encontraron concentraciones elevadas (en comparación con los niveles normales) en los pulmones, ganglios linfáticos hilares, hígado y bazo (ATSDR 2008). Las ratas y los conejillos de indias con exposición intermedia o crónica al clorhidrato de aluminio mostraron acumulación principalmente en los pulmones y cierta acumulación adicional en las glándulas suprarrenales y los ganglios linfáticos peribronquiales. La excreción en seres humanos ocurre a través de la orina y existe una correlación entre la duración de la exposición y las concentraciones urinarias. Los soldados expuestos de 0.2 a 5.3 mg/m<sup>3</sup> de aluminio durante un período de 10 años presentaron vidas medias de aluminio urinario de más de 6 meses en comparación con los 9 días registrados en personas con una exposición de menos de 1 año (ATSDR 2008).

### Exposición Dérmica

Se realizó un estudio aplicando clorhidrato de aluminio en las axilas de dos individuos, en las conclusiones se establece que un 0.012% del aluminio aplicado se absorbió a través de la piel (ATSDR 2008). Otro estudio realizado esta vez con ratones reportó concentraciones elevadas en el hígado, cerebro, pulmones y riñones, después de una exposición de 0.04 mg/día durante 20 días de gestación (ATSDR 2008). No se encontraron estudios sobre la excreción del aluminio después de la exposición dérmica en seres humanos o animales (ATSDR 2008).

## **Toxicidad**

### Efectos no Cancerígenos

Los estudios sobre la toxicidad del aluminio mediante exposición por inhalación, oral o dérmica son limitados y con frecuencia contradictorios o aportan información limitada (es decir no especifican la dosis, la forma o la biodisponibilidad del aluminio o la identidad y la concentración de otros compuestos con exposición concomitante), haciendo así difíciles las evaluaciones de la toxicidad específica del aluminio.

### Exposición Oral

El aluminio está presente en toda la dieta de los seres humanos y los animales, y se utiliza en los aditivos alimenticios, los envases, el agua potable y las medicinas. Se estima que la ingesta alimenticia normal de los seres humanos es de 0.10 a 0.12 mg/kg/día en adultos (ATSDR 2008). Se reportó que la exposición oral al fosforo de aluminio es tóxica para los seres humanos (incluyendo los efectos cardiovasculares y gastrointestinales después de una exposición accidental aguda o por un intento de suicidio), aunque se considera el resultado de la formación de gas fosfina altamente tóxico y no del aluminio en sí. Se realizó diversos estudios sobre toxicidad oral en animales, desafortunadamente la tasa base de la ingesta alimenticia con frecuencia no se informa, lo que subvalora las concentraciones totales de la ingesta. Algunos efectos del aluminio después de una ingesta oral en roedores incluyen ataxia, expansión y arrastre de las extremidades posteriores y parálisis de ratones madre expuestos a aproximadamente 184 mg/kg/día o 250 mg/kg/día en forma de lactato de aluminio durante la gestación y la lactancia (ATSDR 2008).

Estudios sobre la absorción oral del aluminio encontraron NOAEL variando entre los 0.6 mg/kg/día en ratones hembra y todas las ratas, después de 5 o 7 semanas (ratones) y una exposición de 2.5 años (ratas) al cloruro de aluminio y sulfato de aluminio y potasio (administrados en la comida y el agua), y los 979 mg/kg/día en ratones (administrados en la ingesta alimenticia en forma de sulfato de aluminio y potasio durante 20 meses) (ATSDR 1999). Los NOAEL por exposición oral fluctuaron entre los 130 mg/kg/día (administrados en forma de lactato de aluminio en la ingesta alimenticia durante un periodo de 6 semanas) en ratas (causando disminución de la

actividad neurológica total, vertical y horizontal; disminución del periodo diurno y acortamiento de los periodos de actividad) y los 770 mg/kg/día (administración una sola vez a través de sonda en forma de cloruro de aluminio) en ratones machos (correspondientes a una  $DL_{50}$ ) (ATSDR 2008).

### Exposición por Inhalación

Estudios ocupacionales revelaron toxicidad después de una exposición por inhalación, incluyendo respiración sibilante, disnea y daños a la función pulmonar (después de la exposición a vapores de aluminio no especificados) y fibrosis pulmonar después de la exposición a polvos contendores de aluminio. Las exposiciones ocurrieron en forma simultánea con exposición a muchos otros químicos tóxicos (ATSDR 2008). Una persona expuesta en forma crónica al polvo de aluminio y al aluminio metálico mostró efectos reversibles en los pulmones (granulomas epitelioides tipo sarcoidosis). Los efectos neurológicos en trabajadores expuestos en forma crónica se limitan a efectos sub-clínicos que incluyen daños a la memoria, cambios en el electroencefalograma (EEG), coordinación vista-mano y destrezas motoras; aunque en los estudios no se caracterizó adecuadamente la exposición al aluminio y su validez se cuestiona (ATSDR 2008). En estudios con hámsters encontró aumentos en el peso absoluto de los pulmones después de una exposición de 3 días a  $\geq 7 \text{ mg/m}^3$  y se corresponden a hallazgos similares realizados en conejos después de exposiciones a  $43 \text{ mg/m}^3$  durante 5 días. En otro estudio con duración de 24 meses, se observó una reducción en el peso corporal en ratas expuestas a  $6.1 \text{ mg/m}^3$  de clorhidrato de aluminio.

Estudios sobre absorción por inhalación con animales de laboratorio encontraron NOAEL para el aluminio fluctuando entre los  $0.061 \text{ mg/m}^3$  después de una exposición por largo tiempo al clorhidrato de aluminio en ratas y conejillos de indias y los  $100 \text{ mg/m}^3$  después de una exposición durante 5 días al polvo de aluminio, durante 4 horas/día en ratas (ATSDR 2008). Los LOAEL por inhalación oscilaron entre los  $0.61 \text{ mg/m}^3$  en ratas y conejillos de indias debido a la exposición al clorhidrato de aluminio durante 6 meses, 5 días/semana, 6 horas/día (causando incrementos de macrófagos alveolares y lesiones en los pulmones en ambas especies) y los  $200 \text{ mg/m}^3$  en ratones después de una exposición de 5 días al polvo de aluminio (causando microgranulomas multifocales en los pulmones) (ATSDR 2008).

### Exposición Dérmica

Los estudios sobre la exposición dérmica son limitados, sin embargo los efectos de la exposición al aluminio incluyen daños a la piel en ratones hembra, conejos y conejillos de indias grandes después de aplicar 10% de cloruro de aluminio (0.005 a 0.1 g Al) o nitrato de aluminio (0.006 a 0.013 g Al), aunque en ninguna otra forma después de un estudio de exposición de 5 días (ATSDR 2008). Estudios sobre el aumento de incidencias de la enfermedad de Alzheimer después de la aplicación de desodorantes

contentivos aluminio en seres humanos establecen una tendencia ( $p=0.03$ ) a un mayor riesgo con el aumento de uso de estos desodorantes (ATSDR 2008).

#### Dosis Referencial para la Exposición Oral Crónica (DR)

*Health Canada* (2009) no ha desarrollado una ingesta diaria tolerable para el aluminio (*Health Canada* 2009).

USEPA derivó una DR provisional correspondiente a 1 mg/kg/día para el aluminio (USEPA 2009b). El USEPA IRIS no dispone de una DR para el aluminio (2009a).

#### Concentración Referencial para la Exposición por Inhalación Crónica (CR)

*Health Canada* (2009) no ha desarrollado una concentración tolerable para el aluminio.

El USEPA IRIS no dispone de una CR para el aluminio, sin embargo existe una establecida en el RAIS (2009). La concentración referencial para inhalación crónica corresponde a  $5.00\text{E-}03 \text{ mg/m}^3$ . La CR se basa en un estudio realizado por Hosovski (1990), donde se evaluó los efectos críticos del aluminio en el deterioro psicomotriz y cognitivo de los seres humanos. La CR posee un factor de modificación de 1 y un factor de incertidumbre de 300 y la confianza general se considera de baja a media. La CR convertida en una dosis referencial para inhalación crónica corresponde a  $1.43 \text{ E-}03 \text{ mg/kg/día}$ .

#### Efectos Cancerígenos

*Health Canada* (2009) y USEPA (2009a) no han evaluado la carcinogenicidad del aluminio.

#### Riesgo de Desarrollar Cáncer por Exposición Oral

Actualmente no se dispone de un factor de pendiente oral para el aluminio (*Health Canada*, 2009 y USEPA, 2009a).

#### Riesgo de Desarrollar Cáncer por Exposición a la Inhalación

Actualmente no se dispone de un factor de pendiente oral para el aluminio (*Health Canada*, 2009 y USEPA, 2009a).

## **Arsénico**

### **Farmacocinética**

#### Exposición Oral

Los estudios en seres humanos muestran que tanto los arseniatos como los arsenitos se absorben en gran cantidad a través del tracto gastrointestinal; la evidencia se encuentra en el pequeño porcentaje de arsénico eliminado directamente en las heces (la absorción de sales de arsénico insoluble después de una exposición oral es mucho menor que la absorción de los arseniatos y arsenitos). Se estima que la absorción de arseniatos y arsenitos a través del tracto gastrointestinal es del orden del 95% y la excreción urinaria varía entre el 55 y el 80% de la tasa de ingesta diaria. Estudios sobre la biodisponibilidad del arsénico realizados en animales indican que la absorción del arsénico ingerido en polvo o del suelo es considerablemente menor que la absorción del arsénico a partir de sales ingeridas (ATSDR 2000). La biodisponibilidad del arsénico a partir del suelo se reduce por la baja solubilidad y accesibilidad debido a la presencia de otros componentes de la matriz del suelo (Davis 1992 según se cita en ATSDR 2000). En un estudio en el que se incubó suelo contaminado con arsénico proveniente de minas y fundiciones en ácido estomacal simulado se encontró que sólo una porción del arsénico (entre 3% a 50%) se solubilizó. El arsénico soluble o biodisponible estimado coincide en gran forma con la biodisponibilidad estimada para las mismas muestras de suelo.

#### Exposición por Inhalación

El arsénico inhalado por transmisión aérea se deposita rápidamente en el tracto respiratorio y se absorbe en el flujo sanguíneo (Hrudey 1996) y el tamaño y la solubilidad de los aerosoles que contienen arsénico influyen en la extensión del depósito, la retención y la depuración de los pulmones. Un estudio sobre la absorción del arsénico en un grupo de pacientes con cáncer pulmonar indicó que aproximadamente el 40% del arsénico contenido en el humo de los cigarrillos se depositó en los pulmones, calculándose la absorción entre 75 a 85%, originando una absorción total de aproximadamente 30 a 40% del arsénico contenido en dicho humo. La Conferencia de Higienistas Industriales del Gobierno de los Estados Unidos (ACGIH 2001) indica que aproximadamente el 77% de las partículas transportadas por el aire con un diámetro de 10  $\mu\text{m}$  se deposita generalmente en el tracto respiratorio. La Organización Mundial de la Salud (OMS 1981, según se cita en ATSDR 2000) indica que la biodisponibilidad del As (III) soluble al agua depositado podría ser hasta de 85 a 90%. Los trabajadores de fundiciones expuestos a trióxido de arsénico absorbieron aproximadamente entre 40 y 60% de la dosis inhalada estimada (Vahter 1986, según se cita en ATSDR 2000). Vahter también demostró que la eliminación de arsénico a través de la orina es relativamente rápida, ya que la excreción aumentó en pocas horas posteriores a que los trabajadores comenzaron el trabajo de la semana y disminuyó durante el fin de semana.

### Exposición Dérmica

Se han realizado diversos estudios sobre la absorción del arsénico inorgánico a través de la piel en seres humanos y animales. Wester (1993, según se cita en Hrudey 1996) estudió la absorción del arsénico del agua y el suelo tanto en seres humanos como en monos. Se realizó pruebas de la absorción del arsénico y de arsénico mezclado con suelo a través de la piel utilizando arsénico marcado radioactivamente ( $H_3AsO_4$ ) en cadáveres y se encontró que únicamente el 0.8% del arsénico en la solución de agua penetra la piel de los seres humanos en comparación con el 2 a 6% que penetró la piel abdominal de los monos; entre 3% y 4.5% del arsénico mezclado con suelo se absorbió por la piel de los monos mientras que el 1.9% por la piel humana.

## **Toxicidad**

### Efectos no Cancerígenos

#### Exposición Oral

Se reportaron efectos respiratorios como edemas pulmonares, dificultad respiratoria y bronquitis hemorrágica después de casos de envenenamiento agudo con arsénico por vía oral, originados por el consumo de dosis de 8 mg/kg. Los efectos se pudieran considerar como secundarios originados por el daño al sistema cardiovascular. Se estableció que altas dosis orales de arsénico causan arritmias cardíacas.

La enfermedad del pie negro (pérdida de la circulación en los dedos de las manos y de los pies) es el principal efecto de la exposición crónica al arsénico en el sistema cardiovascular y se demostró en una zona de Taiwán con altos niveles de arsénico en el agua potable. También se observan casos similares aunque menos graves, de enfermedades vasculares periféricas como la enfermedad de Raynaud y la gangrena de dedos de las manos y de los pies en poblaciones expuestas en forma crónica a concentraciones elevadas de arsénico en el agua potable en Bangladesh, México y Chile (ATSDR 2000). La neuropatía periférica, caracterizada por el entumecimiento de manos y pies, corresponde al efecto colateral neurológico más común producto de la exposición crónica al arsénico por vía oral. Los síntomas mejoran una vez que la exposición se detiene pero la recuperación tiende a ser lenta e incompleta (ATSDR 2000).

El consumo oral de arsénico inorgánico ocasiona malestar gastrointestinal y los síntomas usualmente incluyen náuseas, vómitos y diarrea (ATSDR 2000). Los síntomas resultan de la irritación de la mucosa gastrointestinal y disminuyen varios días después de la exposición. Con frecuencia se observa en seres humanos expuestos oralmente al arsénico, la depresión de los glóbulos rojos (anemia) o de los glóbulos blancos (leucopenia) (ATSDR 2000). Se observó daños a las células hepáticas únicamente en algunos casos de envenenamiento agudo con arsénico y usualmente no se asocian con la exposición crónica de bajo nivel al arsénico por vía oral. Las lesiones

cutáneas como hiperqueratinización de la piel en las palmas de las manos y las plantas de los pies, formación de callos y verrugas y la hiperpigmentación o hipopigmentación de la piel son los primeros signos clínicos (ATSDR 2000).

Existe evidencia donde se sugiere que el arsénico pudiera causar efectos en el desarrollo, se reportó el caso de una madre con ingesta de arsénico en la semana 30 de su embarazo, originando el nacimiento de su bebé prematuro quien murió varios días después al presentar hemorragia pulmonar grave, análisis posteriores revelaron altos niveles de arsénico en el hígado, los riñones y el cerebro del bebé (Lugo 1969 en ATSDR 2000). Estudios más recientes donde se evalúa los niveles normales de arsénico en el agua potable, los defectos cardíacos congénitos y los abortos espontáneos, no arrojan resultados concluyentes debido a los reducidos tamaños de la muestra y a la presencia de múltiples contaminantes (ATSDR 2000). La exposición a los polvos de arsénico en el lugar de trabajo originó casos de dermatitis por contacto y si el contacto ocurre de manera repetida pudiera generar sensibilización al arsénico en entornos ocupacionales.

Los estudios no identifican sub-poblaciones de seres humanos con susceptibilidad particular al arsénico. Sin embargo es posible que las personas con menos capacidad de generar la metilación del arsénico en el hígado, mecanismo por el cual la toxicidad del arsénico se reduce, pudieran ser más susceptibles (ATSDR 2000). La menor capacidad del hígado de generar la metilación del arsénico se podría deber a la falta de colina o metionina en la dieta y la menor capacidad de metilación del hígado no parece ser el resultado de una enfermedad hepática, al menos no con niveles bajos de exposición al arsénico (ATSDR 2000).

#### Exposición por Inhalación

La mayor parte de la información sobre la exposición por inhalación de arsénico en seres humanos se deriva de entornos ocupacionales tales como fundiciones y plantas químicas en donde la forma predominante del arsénico transportado por el aire es el polvo de trióxido de arsénico. Los trabajadores expuestos a polvos de arsénico en el aire experimentaron irritación de las membranas mucosas de la nariz y la garganta que podrían originar laringitis, bronquitis o rinitis; existe cierta evidencia de que el arsénico inorgánico inhalado también podría tener efectos cardiovasculares. Estudios con mortalidad de la cohorte realizados a trabajadores expuestos al arsénico en varias fundiciones reportaron sobre el aumento del riesgo de mortalidad a partir de enfermedades cardiovasculares (es decir cardiopatía isquémica y enfermedad cerebrovascular) y efectos neurológicos periféricos. Sin embargo diversos factores (exposición al cobre y a otros metales) pudieran alterar las conclusiones. Varios estudios reportan la presencia de náuseas, vómitos y diarreas en trabajadores con envenenamiento agudo por arsénico después de la exposición por inhalación en el lugar de trabajo. Se observó dermatitis (hiperpigmentación, foliculitis y ulceraciones

superficiales) en 11 empleados de un departamento de una fundición de estaño en Malasia (de un total de 500 empleados en la planta) expuestos a concentraciones promedio de óxido de arsénico de 0.005 a 0.014 mg As<sub>2</sub>O<sub>3</sub>/m<sup>3</sup>. También existen varios estudios que sugieren que la exposición por inhalación al arsénico podría causar un aumento de las incidencias de abortos espontáneos, aumentos significativos en las incidencias de malformaciones congénitas y una reducción significativa del peso promedio de nacimiento en empleadas de fundiciones en Suecia (ATSDR 2000).

No se encontraron estudios sobre los efectos respiratorios en seres humanos expuestos a arsénicos orgánicos. La exposición de ratas y ratones a altas concentraciones de arsénico por corto tiempo causó dificultad respiratoria y la necropsia de animales reveló pulmones de color rojo brillante con manchas oscuras, también se observó dificultad respiratoria en ratas y ratones expuestos a altos niveles de arsénico.

#### Exposición Dérmica

Diversos estudios con seres humanos expuestos a polvos de arsénico en su lugar de trabajo reportaron que el arsénico inorgánico (usualmente trióxido de arsénico) puede causar dermatitis por contacto (eritema e hinchazón, con pápulas y vesículas). También se reportó que la aplicación de arsénico orgánico en la piel de conejos origina una leve irritación dérmica.

#### Ingesta Diaria Tolerable (IDT) y Dosis Referencial (DR) para la Exposición Crónica Oral

Actualmente no se dispone de un valor para la ingesta diaria tolerable del arsénico y sus compuestos inorgánicos por parte de *Health Canada* (*Health Canada* 2004).

Se observó un aumento en lesiones cutáneas y enfermedades vasculares tales como la enfermedad del pie negro en personas que consumieron agua con elevados niveles de arsénico por largos periodos de tiempo. Sobre la base de esta población se determinó un NOAEL de 0.009 mg/L (o 8E-4 mg/kg/día) y un LOAEL de 0.17 mg/L de arsénico (~0.014 mg/kg/día) (USEPA 2004). USEPA desarrolló una dosis referencial oral de 3E-4 mg/kg/día dividiendo el NOAEL por un factor de seguridad de 3 con el fin de representar los pocos datos existentes sobre los posibles efectos del arsénico en la toxicidad reproductiva (USEPA 2004).

#### Concentración Tolerable (CT) y Concentración Referencial (CR) para la Exposición Crónica por Inhalación

Actualmente no se dispone de un valor para la concentración tolerable de arsénico y sus compuestos inorgánicos por parte de *Health Canada* (*Health Canada* 2004).

Actualmente no se dispone de una concentración referencial para la exposición crónica por inhalación de arsénico (USEPA 2004).

### Efectos Cancerígenos

*Health Canada* clasificó al arsénico y sus compuestos inorgánicos en el grupo I, es decir cancerígenos para los seres humanos, según la carcinogenicidad documentada posterior a la exposición oral y por inhalación (*Health Canada* 1993). Los cánceres humanos asociados con la exposición ocupacional a los compuestos de arsénico incluyen el cáncer de pulmón, estómago, colón, hígado y sistema urinario; correspondiendo a la exposición por inhalación la trayectoria más significativa (*Health Canada* 1993). También se caracterizó la exposición oral y un estudio taiwanés encontró cánceres de piel asociados con la ingesta de arsénico en agua potable (*Health Canada* 1993).

USEPA clasificó el arsénico inorgánico en el grupo A, es decir agente cancerígeno conocido para los seres humanos por exposición oral e inhalación según el aumento de mortalidad producido por cáncer pulmonar en múltiples poblaciones humanas (expuestas principalmente a través de la inhalación), aumento de la mortalidad producido por cánceres en múltiples órganos internos (hígado, riñones, pulmones y vejiga) y aumento en la incidencia del cáncer de piel en poblaciones que consumen agua potable con altos niveles de arsénico inorgánico (USEPA 2004).

### Riesgo de Desarrollar Cáncer por Exposición oral

*Health Canada* derivó un factor de pendiente oral de  $2.8 \text{ (mg/kg/día)}^{-1}$  (*Health Canada* 2004) según el punto final crítico del cáncer de piel. Los datos utilizados para desarrollar el factor de pendiente oral se seleccionaron de la cohorte taiwanesa (Tseng 1968, Tseng 1977, según se cita en *Health Canada* 2004), expuesta hasta 1.82 ppm de arsénico en agua potable, el potencial de cáncer se estimó utilizando un modelo de múltiples fases con el fin de que la concentración correspondiente a un aumento en la prevalencia de cáncer de piel sea de 5%. *Health Canada* recientemente emitió un valor guía preliminar de  $1.8 \text{ (mg/kg/día)}^{-1}$  tomando como base la evaluación de la guía revisada de agua potable (*Health Canada* 2009).

USEPA desarrolló un factor de pendiente del cáncer de  $1.5 \text{ (mg/kg/día)}^{-1}$  para exposición oral, basado en estudios que indican un aumento en la incidencia del cáncer de piel en poblaciones taiwanesas expuestas por vía oral al arsénico en agua potable (Tseng 1968, Tseng, 1977 en USEPA 2004).

### Riesgo de Desarrollar Cáncer Debido a una Exposición por Inhalación

*Health Canada* desarrolló un valor de concentración tumorigénica ( $TC_{05}$ ) para la exposición por inhalación al arsénico y sus compuestos inorgánicos de  $7.8E-3 \text{ } \mu\text{g}/\text{m}^3$

(*Health Canada* 1993, 2004), el valor se basa en un estudio ocupacional en la Fundición Anaconda en Montana el cual descubrió niveles elevados de cánceres pulmonares en empleados que inhalaron arsénico (*Health Canada* 1993). El tamaño del estudio se considera como suficiente para determinar una exposición estimada, sin embargo no se realizaron intentos para validar la exposición estimada por trabajador, sobre la base de una revisión de los registros originales (*Health Canada* 1993). En el año 2004 *Health Canada* convirtió la  $TC_{05}$  en un factor de pendiente de inhalación utilizando la ecuación  $(0.05/(TC_{05} \times 16m^3/día/70.7kg))$ , el factor de pendiente resultante corresponde a  $28.0 (mg/kg/día)^{-1}$ .

La Organización Mundial de la Salud (OMS) dedujo un riesgo unitario tomando como base estudios en poblaciones de seres humanos expuestos en Suecia y los Estados Unidos y su susceptibilidad al cáncer pulmonar. El riesgo se calculó de por vida en  $1.5 \times 10^{-3}$  con una concentración de aire de  $1 \mu g/m^3$ .

### Resumen

## **Bario**

### **Farmacocinética**

#### **Exposición Oral**

Se considera que la exposición oral es la ruta principal de la exposición al bario en seres humanos (ATSDR 1992). Se considera también que la absorción de bario a través del tracto gastrointestinal es muy pobre, estimada en <5% (ATSDR 1992). Mediante experimentos con ratas se descubre que los animales más jóvenes (<22 días de nacidos) absorben aproximadamente 10 veces más cloruro de bario por el tracto gastrointestinal (63% a 84%) en comparación con los animales de más edad (aproximadamente 7%). En perros por ejemplo los niveles séricos de bario indican que la absorción máxima por el tracto gastrointestinal se realiza en el transcurso de 1 hora y la distribución del bario a través de la exposición oral es similar a la exposición por inhalación, con 93% de acumulación en huesos y dientes. El cuerpo no metaboliza el bario, aunque se pudiera transportar e incorporar a complejos metabólicos o tejidos corporales y debido a que se absorbe muy poco por los seres humanos, la mayor parte del bario administrado en forma oral se excreta en las heces, mientras que aproximadamente sólo el 3% se excreta en la orina.

### Exposición por Inhalación

No se establecen las características de la velocidad y extensión de la absorción del bario por inhalación en seres humanos. Sin embargo se han realizado estudios de laboratorio con animales, en hámsters el 65% del bario depositado en la región nasal en forma de cloruro de bario eventualmente se absorbe en el cuerpo (ATSDR 1992). Un estudio con perros encontró que aproximadamente el 50% del bario inhalado en forma de cloruro de bario y el 75% del bario inhalado en forma de sulfato de bario se deposita en la región pulmonar, aproximadamente el 25% se transporta al esqueleto y el resto se excreta en la orina y en las heces durante un periodo de 2 semanas. La vida media biológica del bario es de 8 días en perros y 10 días en ratas. Estudios sobre la distribución del bario a través de la exposición por inhalación en seres humanos determinaron que el bario se deposita principalmente en el esqueleto y los dientes. Los perros que inhalaban cloruro de bario radioactivo presentaron 70% de deposición en los pulmones y los órganos internos (44% en el esqueleto, 13% en la orina y 13% en las heces) con deposición poco significativa en la sangre (1%) y en los músculos (4%). No se encontraron estudios sobre la excreción del bario en seres humanos, pero <1% del cloruro de bario inhalado permanece en los perros después de 5 días.

### Exposición Dérmica

No se encontraron estudios con seres humanos sobre la absorción, distribución o excreción del bario a través de exposición dérmica. Estudios con animales mostraron que se encontró el bario aplicado en la piel de lechones en varias capas de la piel (ATSDR 1992). No se espera que el bario atravesase la piel intacta debido a la alta polaridad de las formas en las cuales se encuentra más comúnmente.

## **Toxicidad**

### Efectos no Cancerígenos

#### Exposición Oral

La mayor parte de los estudios sobre la toxicidad del bario realizados con seres humanos se refieren a exposición oral y los efectos que siguen a una exposición aguda, incluyen debilidad para respirar y parálisis (requiere ventilación mecánica), hipertensión y arritmia cardíaca, malestar gastrointestinal, debilidad muscular progresiva originando parálisis total o parcial, degeneración de los riñones y fallo renal agudo, y en los casos más graves, muerte por paro cardíaco o hemorragia gastrointestinal. Estudios con animales de laboratorio descubrieron acumulación de fluido en la tráquea de ratas (después de una exposición aguda) y aumento de la presión sanguínea después de una exposición oral.

Estudios sobre absorción oral en ratas de laboratorio reportaron NOAEL para el cloruro de bario administrado en agua potable variando entre los 0.054 mg/kg/día (enfocándose en efectos cardiovasculares) y los 198 mg/kg/día en (la misma tasa no tuvo efectos en el sistema cardiovascular, hematológico o inmunológico) (ATSDR 1992). Los LOAEL de bario obtenidos a partir de estudios sobre la absorción oral de cloruro de bario oscilaron entre los 0.54 mg/kg/día en ratas (causando un aumento de la presión sanguínea) y los 277 mg/kg/día en ratas (causando la muerte en el 50% de los machos).

#### Exposición por Inhalación

Se demostró que la inhalación en seres humanos del polvo de sulfato de bario tiene efectos poco significativos en los pulmones (neumoconiosis benigna). En estudios con animales se encontró lesiones pulmonares en ratas después de una exposición intermedia a 3.6 mg/m<sup>3</sup> de polvo de carbonato de bario y broncoconstricción en conejillos de indias después de una exposición a 0.06 mg/m<sup>3</sup>/min de cloruro de bario en aerosol, durante un periodo no especificado (ATSDR 1992).

#### Exposición Dérmica

El polvo del óxido de bario se considera como un irritante dérmico (USEPA 1997). Se esperaría que las sales de bario tengan un efecto local en superficies cutáneas y sería poco probable que se absorban sistemáticamente en gran medida. Se dispone de informes sobre el caso de una persona expuesta al cloruro de bario fundido a través de la piel, sobre irritación cutánea que evalúa el carbonato de bario en animales de laboratorio y sobre un estudio que utilizó el pintado de la piel; en el cual se expuso la piel de ratones a un extracto de hojas del tabaco con hidróxido de bario (ATSDR 1992). Las quemaduras cutáneas desarrolladas en la persona expuesta al cloruro de bario fundido podrían haber contribuido posiblemente al electrocardiograma anormal, vómitos, reducción del potasio en plasma y aumento de los niveles de bario en plasma. Las ratas y los conejos expuestos al carbonato de bario en forma tópica mostraron signos de ulceraciones cutáneas.

#### Dosis Referencial para la Exposición Crónica Oral (DR)

La DR para el bario corresponde a 0.07 mg/kg/día tomando como base el NOAEL de 10 y 7.3 mg/L (ajustado a 0.21 mg/kg/día). Se enfocó en el peso de la evidencia para deducir la DR que a su vez utilizó un estudio experimental y uno epidemiológico con seres humanos y estudios crónicos y sub-crónicos con ratas. En ambos estudios con seres humanos no se encontró efectos en los adultos y en los estudios crónicos y sub-crónicos con ratas se encontró NOAEL de 65 y 45 mg/kg/día y LOAEL de 115 y 75 mg/kg/día para los efectos renales (aumento del peso de los riñones). Se aplicó un factor de incertidumbre total de 3, compuesto por un FI de 1 para representar algunas deficiencias de la base de datos y un factor de 3 para representar la falta de posibles

diferencias entre los adultos y los niños y de estudios adecuados sobre toxicidad en el desarrollo. Se reportó que la confianza en la DR oral para el bario es media debido a la calidad del estudio, la base de datos y el valor de la DR.

#### Concentración Referencial para la Exposición Crónica por Inhalación (CR)

No se dispone de una CR por inhalación aunque los estudios realizados con animales y seres humanos sugieren que el sistema respiratorio es un blanco de la toxicidad para el bario (USEPA 2004). Se estableció una DR<sub>i</sub> a partir de una tabla HEAST alternativa con un valor de 5E-4 mg/kg/día (EPA Región 3 2009).

#### Efectos Cancerígenos

El bario se considera un agente cancerígeno de grupo D, es decir no clasificable como cancerígeno para los seres humanos. La clasificación se basa en la falta de estudios adecuados sobre inhalación, aunque todavía se considera como poco probable que el bario sea cancerígeno para los seres humanos después de una exposición oral (USEPA 2009).

#### Riesgos de Desarrollar Cáncer por Exposición Oral

No se dispone de un factor de pendiente oral para el bario.

#### Riesgos de desarrollar cáncer debido a una exposición por inhalación

No se dispone de un factor de pendiente de inhalación para el bario.

## **Cadmio**

### **Farmacocinética**

#### Exposición Oral y por Inhalación

El principal lugar de absorción del cadmio en los seres humanos después de una inhalación son los alvéolos de los pulmones, mientras que la mayor parte del cadmio ingerido tiende a pasar a través del tracto gastrointestinal sin absorberse y se excreta en las heces (ATSDR 1999). El cadmio absorbido en los pulmones y el tracto gastrointestinal tiende a excretarse muy lentamente y se encuentra en proporciones iguales en la orina y las heces (ATSDR 1999). Los dos principales órganos objetivo para el cadmio son los riñones y el hígado. La vida media del cadmio en el cuerpo humano es muy larga y se estima para los riñones entre 6 a 38 años y en el hígado entre 4 a 19 años (ATSDR 1999). La placenta podría actuar como una barrera parcial a la exposición de feto al cadmio (ATSDR 1999). El cadmio no se metaboliza y se fija a las proteínas y otras moléculas, en particular a la albúmina (una proteína) en el torrente sanguíneo y se transporta al hígado (ATSDR 1999), una vez que el cadmio ingresa al hígado se fija a otra proteína llamada metalotioneína y se libera nuevamente al torrente sanguíneo, posteriormente el cadmio fijado en la metalotioneína se filtra por los glomérulos de los riñones y se reabsorbe por las células del túbulo proximal. Las lisosimas (enzimas fuertes) degradan el complejo de cadmio-metalotioneína y permiten que el cadmio libre se libere en los riñones. El cadmio libre inicia la síntesis de la metalotioneína en las células de túbulo proximal y también puede causar daño excesivo a los riñones.

#### Exposición Dérmica

Actualmente no existe información para determinar la posible absorción del cadmio a través de la ruta de exposición dérmica (ATSDR 1999). Según la poca información existente al parecer se absorbe muy poco cadmio a través de la piel.

### **Toxicidad**

#### Efectos no Cancerígenos

##### Exposición Oral

Altas dosis agudas de cadmio por vía oral (0.07 mg/kg) pudieran causar efectos gastrointestinales como náuseas, vómitos y dolor abdominal (Nordberg 1973, según se cita en ATSDR 1999). La ingesta o inhalación de cadmio puede producir anemia y si se transporta a los intestinos, reducirá la absorción del hierro. Sin embargo en poblaciones con una ingesta alimenticia adecuada de hierro, es probable que la anemia inducida por el cadmio no sea un problema, ya que el aumento de la ingesta compensará la menor absorción (ATSDR 1999). La exposición crónica de cadmio en

conjunto con una mala nutrición puede originar cambios en la forma en que los riñones metabolizan la vitamina D, causando enfermedades óseas dolorosas tales como osteomalacia y osteoporosis (ATSDR 1999). El cadmio causa daños renales especialmente a los túbulos renales en las etapas iniciales y a medida que la enfermedad avanza o la dosis aumenta, también se observa daño glomerular (ATSDR 1999). Existen datos limitados que sugieren que las exposiciones al cadmio en mujeres embarazadas pudieran ocasionar una reducción del peso de sus bebés al nacer (ATSDR 1999). Las poblaciones que podrían ser inusualmente susceptibles a la exposición al cadmio son aquellas con una predisposición genética a una menor capacidad de inducción de la metalotioneína, la enzima que aísla el cadmio. El aumento de la absorción del cadmio mediante el tracto gastrointestinal podría originar que las personas presenten niveles reducidos de calcio y hierro a consecuencia de deficiencias en su dieta (ATSDR 1999). Los infantes y los niños pudieran presentar una reducción de la absorción del cadmio a través del tracto gastrointestinal y mayores concentraciones de cadmio en los huesos.

#### Exposición por Inhalación

La inhalación del cadmio a  $5 \text{ mg/m}^3$  ocasiona edemas pulmonares, traqueobronquitis y neumonitis en los seres humanos (ATSDR 1999).

#### Exposición Dérmica

El cadmio parece tener una toxicidad dérmica relativamente baja según los estudios ocupacionales en los cuales trabajadores que presentaron exposición a altos niveles de polvo de cadmio, no reportaron ningún efecto dérmico, y adicionalmente el cadmio no parece ocasionar sensibilización por el contacto dérmico repetido (ATSDR 1999).

#### Dosis Referencial para la Exposición Crónica Oral (DR)

USEPA desarrolló dosis referenciales orales para el cadmio en los alimentos y el agua y corresponde a  $1\text{E-}3 \text{ mg/kg/día}$  en el caso de los alimentos y  $5\text{E-}4 \text{ mg/kg/día}$  para el agua (USEPA 2004). Se determinó que el nivel más elevado de cadmio en los riñones humanos que no produce proteinuria es  $200 \text{ µg/g}$  de la corteza renal húmeda. Se utilizó un modelo toxicocinético con el fin de determinar el nivel de exposición oral crónica que podría causar una concentración de cadmio en los riñones de  $200 \text{ µg/g}$  de la corteza renal húmeda. El modelo supone que el 0.01% de la carga corporal de cadmio en los riñones se elimina diariamente y que la absorción de cadmio a partir de los alimentos y el agua es de 2.5 y 5%, respectivamente. Se determinó un NOAEL para la exposición de crónica de cadmio a través del agua y de los alimentos de 0.005 y  $0.01 \text{ mg/kg/día}$  también respectivamente. Se aplicó un factor de incertidumbre de 10 a los NOAEL representando así la variabilidad de los seres humanos con el fin de determinar las dosis referenciales para el agua y los alimentos.

### Concentración Referencial para la Exposición Crónica por Inhalación (CR)

Actualmente no se dispone de una CR para el cadmio (USEPA 2004).

### Efectos Cancerígenos

Estudios epidemiológicos demuestran un aumento en la incidencia de cáncer pulmonar en trabajadores expuestos al cadmio mediante la ruta de la inhalación, sin embargo en los estudios no se controlaron factores tales como el nivel de tabaquismo y las exposiciones simultáneas a otros metales, de manera que la relación causal es de algún modo controversial. La exposición oral al cadmio no se asocia al cáncer en seres humanos, sin embargo los estudios disponibles se consideran como inadecuados para evaluar su carcinogenicidad. USEPA clasificó al cadmio en el grupo B2, es decir probable agente cancerígeno para los seres humanos, según datos limitados con respecto a los seres humanos y datos suficientes con respecto a los animales (USEPA 2004)

### Riesgo de Desarrollar Cáncer por Exposición Oral

Actualmente no se dispone de un factor de pendiente oral para el cadmio (USEPA 2004).

### Riesgo de Desarrollar Cáncer Debido a una Exposición por Inhalación

*Health Canada* publicó un factor de pendiente de inhalación de  $42.9 \text{ (mg/kg/día)}^{-1}$  para el cadmio (*Health Canada* 2009).

Se realizó una evaluación cuantitativa del riesgo de desarrollar cáncer debido a la exposición por inhalación y se calculó el riesgo unitario aéreo en  $1.8\text{E-}3 \text{ (}\mu\text{g/m}^3\text{)}^{-1}$  (USEPA 2004).

### **Resumen**

## **Cromo (III y VI)**

### **Farmacocinética**

#### Exposición Oral

La absorción del cromo después de una exposición oral, dérmica o por inhalación depende básicamente de dos factores: el estado de valencia del átomo del cromo y a lo que esté fijado (es decir, la forma del enlace) (ATSDR 2000). La absorción de Cr(VI) es mayor que la de Cr(III) debido a que el ion cromato ( $\text{CrO}_4$ )<sup>-2</sup> puede ingresar a las células mediante la difusión facilitada a través de canales del anión, mientras que Cr(III) se absorbe mediante difusión pasiva o fagocitosis (ATSDR 2000). Estudios sobre exposición oral encontraron que la absorción del Cr(III) en la forma altamente soluble del óxido de cromo no es detectable y la absorción del Cr(III) en forma de compuestos dietéticos es entre 0.5 y 2.0% después de haberse ingerido (ATSDR 2000). El cromo se distribuye a muchos órganos, estudios de autopsias en los Estados Unidos reportan las concentraciones más altas en los riñones, el hígado, los pulmones, la aorta, el corazón, el páncreas y el bazo (al nacer), lo que tiende a disminuir con la edad. Los estudios con animales revelan una distribución similar de cromo después de exposición oral, debido a que la absorción es relativamente baja y la trayectoria principal de excreción son las heces. Un estudio realizado con seres humanos expuestos a Cr(III) (en forma de cloruro de cromo) y Cr (VI) (en forma de cromato de sodio) marcados en forma radioactiva, reportó 99.6% y 89.4% respectivamente en las heces seis horas posteriores a la exposición y 0.5% y 2.1% en la orina 24 horas posteriores a la exposición. Se reportaron niveles similares de excreción fecal en estudios realizados con ratas y hámsters.

#### Exposición por Inhalación

Estudios sobre exposición por inhalación establecen que el cromo se absorbe a través de los pulmones y del tracto gastrointestinal (después de la depuración mucociliar de partículas de los pulmones). En la mayoría de los estudios los compuestos de Cr(VI) se absorbieron más rápidamente en los pulmones que el Cr(III), y se observó que el tamaño y la solubilidad de la partícula, así como la actividad de las macrófagas alveolares afectan las tasas relativas de absorción. Debido a su alto punto de ebullición, la mayor parte del cromo en el aire se encuentra fijado a partículas o cromo disuelto en pequeñas gotas y no en forma gaseosa. Posterior a la exposición por inhalación en seres humanos, el cromo se distribuye a los ganglios linfáticos hilares, los pulmones, el bazo, el hígado, los riñones y el corazón luego de una exposición ocupacional (ATSDR 2000). El cromo también se puede transferir al feto a través de la placenta y a los infantes a través de la leche materna. En estudios con animales se encontró que los órganos afectados corresponden a los mismos. Los trabajadores expuestos a compuestos de Cr(VI) poseen concentraciones urinarias más altas de cromo en comparación con los trabajadores expuestos al Cr(III).

### Exposición Dérmica

Los estudios sobre exposición dérmica demuestran que el cromo también se absorbe en forma transdérmica, dependiendo la tasa de transferencia de la integridad de la piel (ATSDR 2000). Se observó toxicidad sistémica en seres humanos después de una exposición dérmica a una mezcla de compuestos de cromo. Como ejemplo, catorce (14) días después de la exposición a una pomada contentiva de cromato de potasio con el fin de tratar la escabiosis, se encontró cromo en la sangre (2 a 5 mg/100 mL), orina (8 mg/L), heces (0.61 mg/100 g) y contenidos estomacales (0.63 mg/100 mL); un caso preexistente de escabiosis o necrosis que causó agrietamiento de la piel podría haber facilitado la absorción. También se observó la absorción dérmica de los animales en conejillos de indias debido a que en estudios con marcadores radioactivos se reportó la distribución del Cr(III y VI) en la sangre, el bazo, la médula ósea, los ganglios linfáticos, la orina y los riñones, con mayor absorción de la forma (VI). La información referente a la excreción del cromo después de una exposición dérmica es limitada, el estudio con seres humanos en donde se aplicó una pomada de cromato de potasio, encontró 8 mg/L de cromo en la orina y 0.61 mg/100 g en las heces 14 días posteriores a la exposición.

### Efectos no Cancerígenos

#### Exposición Oral

Se conoce que la ingesta accidental o intencional de compuestos de cromo causa la muerte en los seres humanos, las autopsias revelan efectos incluyendo edemas, bronquitis grave, bronconeumonía aguda, cambios hipóxicos tempranos en el miocardio, congestión hepática y necrosis del hígado, los túbulos renales y el tracto gastrointestinal (ATSDR 2000). Los efectos gastrointestinales causados por la ingesta de 7.5 mg/kg de Cr(VI) incluyeron dolor abdominal y vómitos (antes de la muerte). Los efectos hematológicos a raíz de la absorción oral en seres humanos incluyen la reducción del contenido de hemoglobina y hematocritos y un aumento del recuento sanguíneo, recuento de reticulocitos y hemoglobina en plasma 4 días después de la ingesta de dicromato de potasio (Cr(VI)). El daño hepático después de la ingesta de Cr(VI) incluyó ictericia, aumento de la bilirrubina y aumento de la deshidrogenasa láctica en suero con daño renal que incluye fallo renal agudo, con proteinuria y hematuria. Un estudio con ratas reportó que la exposición oral por sonda de 13.5 mg/kg/día de Cr(VI) en forma de cromato de potasio durante 20 días originó un aumento de las acumulaciones de lípidos, reubicación de las enzimas hepáticas y un aumento de la acumulación de lípidos, acumulación de triglicéridos y fosfolípidos en diferentes regiones de los riñones. Se observaron disminuciones significativas en el aumento del peso corporal en un estudio con ratas expuestas a 42 mg/kg/día de Cr(VI) durante 12 semanas (causando una disminución del 19%) y 6 mg/kg/día durante 12 semanas (causando una disminución del 10%). También se reportaron efectos en el desarrollo y la reproducción de animales en estudios de exposición oral.

Los estudios de exposición oral del cromo (III) son contradictorios, presentando NOAEL variando entre los 9 mg/kg/día en ratas (administrados diariamente en los alimentos durante 20 semanas) y los 2040 mg/kg/día en ratas (administrados en los alimentos durante 2 años, 5 días/semana). Los LOAEL con exposición oral de cromo (III) en ratas oscilaron entre los 5 mg/kg/día (administrados en agua durante 12 semanas), causando la disminución del peso corporal y los 2365 mg/kg/día después de una sola dosis por sonda con agua, causando la muerte en el 50% de la población (ATSDR 2000).

Estudios de exposición oral de cromo (VI) encontraron NOAEL variando entre los 1.1 mg/kg/día en ratones machos (administrados durante 9 semanas en los alimentos) y los 53.2 mg/kg/día en ratones hembras (administrados en agua durante 9 días, para los días de gestación 6 a 14). Los LOAEL orales para el cromo (VI) fluctuaron entre los 0.036 mg/kg/día en seres humanos (administrados una sola vez, causando dermatitis) y los 811 mg/kg/día en ratones machos (administrados una sola vez, correspondientes a un valor de  $DL_{50}$ ) (ATSDR, 2000).

#### Exposición por Inhalación

Estudios sobre la toxicidad del cromo después de una exposición por inhalación reportan que el tracto respiratorio es el objetivo principal en los seres humanos y después de una exposición a concentraciones elevadas de cromo se presentaron casos de disnea, tos y respiración sibilante (ATSDR 2000). También se observa que las exposiciones inmediatas y crónicas aumentan el riesgo de desarrollar enfermedades respiratorias no cancerígenas que podrían causar la muerte. La exposición ocupacional regular ocasionó dolor estomacal, úlceras en el duodeno, gastritis, cólicos estomacales y indigestión frecuente (la duración promedio de la exposición fue de 7.5 años y las concentraciones medias fueron de  $0.004 \text{ mg/m}^3$  de  $\text{Cr(VI)}$ ). Los efectos hepáticos incluyen el trastorno de las células del hígado, necrosis, infiltración de linfocitos e histiocitos y aumento de las células de Kupffer. El daño renal se manifiesta por la presencia de cilindros de glóbulos blancos y glóbulos rojos en la orina.

Estudios sobre la inhalación del cromo (III) encontraron NOAEL entre los  $0.022 \text{ mg/m}^3$  en seres humanos (a raíz de la mezcla de  $\text{Cr(III)}$ , (VI) y cromita, durante un periodo de 8 años) hasta los  $1.99 \text{ g/m}^3$  (también en seres humanos, a raíz de una mezcla de  $\text{Cr(III)}$  y (VI) después de una exposición crónica (ATSDR 2000). El LOAEL para cáncer de pulmón a partir de la exposición al cromo (III) corresponde a  $0.04 \text{ mg/m}^3$  en seres humanos durante 1 a 49 años de exposición ocupacional (ATSDR 2000).

Estudios sobre la inhalación de cromo (VI) encontraron NOAEL variando desde  $0.022 \text{ mg/m}^3$  en seres humanos (a raíz de una mezcla de  $\text{Cr(III)}$ , (VI) y cromita durante un periodo de 8 años) hasta los  $1.99 \text{ g/m}^3$  (también en seres humanos, a raíz de una

mezcla Cr (VI) y (III) después de una exposición crónica (duración no especificada) (ATSDR 2000). Se reportó un LOAEL para el cromo (VI) de 0.002 mg/m<sup>3</sup> después de 0.2 a 23.6 años de exposición ocupacional en seres humanos (causando atrofia de la mucosa nasal y leve disminución de la función pulmonar) (ATSDR 2000).

#### Exposición Dérmica

La absorción después de una exposición dérmica al Cr(VI) aumenta debido a la naturaleza cáustica de muchos compuestos de Cr(VI) y con frecuencia origina quemaduras y toxicidad sistémica (ATSDR 2000). Estudios ocupacionales sobre la exposición dérmica reportan que el contacto directo con polvo y emanaciones de cromo origina irritación de la nariz y la garganta. Un estudio en donde se aplicó una pomada contentiva de cromato de potasio a los participantes (para tratar la escabiosis) descubrió efectos cardiovasculares que incluyen pulso débil y marcadamente dicrótico, nefritis aguda, leucocitosis grave y síntomas de anemia hemolítica (ATSDR 2000). La dermatitis por contacto en personas sensibles y otras irritaciones cutáneas incluyen quemaduras, ampollas y úlceras en la piel. En un estudio de trabajadores con cromato en los Estados Unidos, el 50% del grupo de estudio presentó úlceras o cicatrices en la piel. Los estudios con animales reportan efectos dérmicos similares después de una exposición, con una aplicación de 42 a 55 mg/kg de Cr(VI), los conejos mostraron efectos tales como inflamación, edemas y necrosis de la piel.

### **Valores Referenciales de Toxicidad – Puntos Finales no Cancerígenos**

#### Dosis Referencial para la Exposición Oral Crónica (DR)

USEPA estableció una DR para el Cr(III) (sales solubles) de 1.5 mg/kg/día basada en un estudio de alimentación crónica a ratas (Ivankovic y Preussman 1975, según se cita en USEPA 1998a) (efectos no especificados) con un NOAEL de 5% de Cr<sub>2</sub>O<sub>3</sub> administrado en la dieta durante 5 días/semana y 600 comidas (ajustadas a 1,468 mg/kg/día) (USEPA 1998a). El factor de incertidumbre total fue de 100 incluyendo un factor de 10 para la conversión de interespecies y otro factor adicional de 10 para proteger a las sub-poblaciones sensibles. Se utilizó un factor de modificación de 10 con el fin de representar las deficiencias en la base de datos. La confianza se considera baja por la calidad del estudio, la base de datos y el valor de la DR; debido a la falta de (a) una metodología de estudio y resultados detallados, (b) datos que sustenten una dosis alta y (c) un nivel de efecto observado en cualquier dosis (es decir se asignó el NOAEL a la dosis más alta de los ensayos).

La DR para el Cr(VI) corresponde a 3E-3 mg/kg/día, lo que refleja una mayor toxicidad que con el Cr(III), según un estudio con agua potable realizado con ratas durante 1 año. El NOAEL se reportó como 25 mg/L K<sub>2</sub>CrO<sub>4</sub> (ajustado a 2.5 mg/kg/día) (USEPA, 1998b), el factor de incertidumbre total fue de 300, compuesto por un factor de 10 para la conversión de interespecies, un factor de 10 para proteger a las sub-poblaciones

sensibles y un factor adicional de 3 para la duración de la exposición del estudio principal que no fue de por vida. Se reportó la confianza en la DR oral como baja debido al pequeño número de personas que participaron del ensayo, a la poca cantidad de parámetros medidos y a la falta de efecto tóxico en la dosis más alta del ensayo. La confianza en la base de datos se considera también como baja debido a la falta de calidad de los estudios de soporte y a la falta de características de la toxicidad en el desarrollo.

#### Concentración Referencial para la Exposición Crónica por Inhalación (CR)

Actualmente no se dispone de La CR del Cr(III) en forma de sales insolubles debido a la falta de datos de ensayos adecuados (USEPA 1998a).

La CR del Cr(VI) se divide según su estado físico en vapores de ácido de cromo /aerosoles disueltos y partículas.

- La CR del Cr(VI) en forma de *vapores de ácido de cromo /aerosoles disueltos* correspondió a  $8\text{E-}6 \text{ mg/m}^3$  según un estudio ocupacional sub-crónico con seres humanos (con un efecto crítico de atrofia del tabique nasal) (USEPA 1998b). No se determinó un valor de NOAEL, sin embargo el LOAEL se reporta como  $2\text{E-}3 \text{ mg/m}^3$  (ajustado a un equivalente de  $7.14 \text{ E-}4 \text{ mg/m}^3$  para seres humanos). El factor de incertidumbre para esta CR es 90, y la confianza en este estudio, la base de datos y el valor de la CR se considera como baja debido a las incertidumbres sobre las características de la exposición y al papel del contacto directo en el efecto crítico (los estudios de soporte se consideran igualmente inciertos con respecto a las características de la exposición).
- La CR del Cr(VI) en forma de *partículas* es  $1\text{E-}4 \text{ mg/m}^3$  según un análisis con dosis de referencia (BMD) de un estudio sub-crónico con ratas, con lactato deshidrogenasa en el fluido del lavado broncoalveolar como el efecto crítico. La BMD correspondió a  $0.016 \text{ mg/m}^3$  (ajustada a una concentración equivalente de  $0.034 \text{ mg/m}^3$  para seres humanos) y el factor de incertidumbre es 300. La confianza en el estudio y el valor de la CR se considera como medio debido a las incertidumbres con respecto a los efectos en las vías respiratorias superiores, el sistema reproductor y los riñones como resultado de la exposición a partículas de Cr(VI).

ATSDR (2000) desarrolló un nivel mínimo de riesgo por inhalación intermedia (NMR) para el cromo (VI) (dicromato de sodio) de  $0.001 \text{ mg de cromo (VI)/m}^3$  en forma de compuestos de partículas de acuerdo a un estudio realizado con ratas por Glaser 1990, según se cita en ATSDR 2000). Se determinó una dosis comparativa de  $0.016 \text{ mg de cromo (VI)/m}^3$  sobre la base de alteraciones en la lactato deshidrogenasa del fluido del lavado bronquial en ratas. La concentración comparativa se ajustó para una exposición inminente y se utilizó un factor de incertidumbre de 30 para deducir el NMR por inhalación intermedia. En el factor de incertidumbre se incluyó un factor de 3 con el fin

de representar la extrapolación de animales a humanos y un factor de 10 por la disponibilidad de seres humanos. Se puede aplicar un factor de incertidumbre adicional al NMR por inhalación intermedia para aproximar un NMR por inhalación crónica, originando un NMR por inhalación crónica de  $1\text{E-}4 \text{ mg/m}^3$ .

### Efectos Cancerígenos

USEPA clasificó al cromo (III) como un cancerígeno del grupo D, es decir no clasificable como cancerígeno para los seres humanos, debido a la falta de información con respecto a los seres humanos y a los datos inadecuados de estudios con animales (USEPA 1998a). La información sobre exposiciones de seres humanos al Cr(III) sólo se dispone con referencia a exposiciones concomitantes al Cr(VI). Los estudios sobre exposición oral en ratas y ratones demuestran un potencial cancerígeno negativo. Los estudios sobre la inhalación de Cr(III) en animales de laboratorio no ocasionaron la reducción de la incidencia de tumores pulmonares (USEPA 1998a). La Agencia Internacional para la Investigación del Cáncer (IARC 1990) clasificó al cromo (III) en el grupo 3, es decir no clasificable con respecto a la carcinogenicidad para los seres humanos.

El cromo (VI) se clasifica como un cancerígeno del grupo A, es decir cancerígeno conocido para los seres humanos, mediante la ruta de exposición por *inhalación* (USEPA 1998b). En estudios con seres humanos se reporta cáncer pulmonar, según datos que concuerdan con estudios realizados con animales, los tipos de tumor incluyen tumores en el punto de inyección intramuscular en ratones y ratas, tumores en el área de implantes intrapleurales en ratas, tumores en el área de implantación intrabronquial en ratas y sarcomas en el punto de inyección subcutánea en ratas (USEPA, 1998b). No ha sido posible determinar la carcinogenicidad de la ruta de exposición oral y en consecuencia el Cr(VI) se clasifica en el grupo D, es decir no clasificable. La Agencia Internacional para la Investigación del Cáncer (IARC 1990) clasificó al cromo (VI) en el grupo 1, es decir cancerígeno para los seres humanos.

### ***Genotoxicidad (Incluyendo Mutagenicidad)***

#### **Cromo (III)**

En general el Cr(III) no resultó mutágeno en ensayos bacterianos cuando se analizó con o sin activación metabólica exógena (Venitt y Levy 1974; Petrelli y Deflora 1977, 1978a,b; según se cita en USEPA 1998a). Un estudio con *Bacillus subtilis* encontró una respuesta mutagénica débil con el Cr (III) en comparación con el Cr(III) (Nakamuro 1978 según se cita en USEPA 1998a,c).

La información referente a la interacción del Cr(III) con el ADN es contradictoria debido a que se encontró que diversos compuestos de Cr(III) son clastogénicos, por ejemplo el  $\text{CrCl}_3$  en células de BALB/c (Raffetto 1977, según se cita en USEPA 1998c) y células

de hámsters chinos Don (Ohno 1982, según se cita en USEPA 1998c);  $\text{CrCl}_3$ ,  $\text{Cr}(\text{NO}_3)_3$ ,  $\text{KCr}(\text{SO}_4)_2$ , o  $\text{Cr}(\text{CH}_3\text{COO})_3$  en células ováricas de hámsters chinos (Levis y Majone 1979, según se cita en USEPA 1998c) y  $\text{Cr}(\text{CH}_3\text{COO})_3$  en leucocitos humanos cultivados (Ohno 1982, según se cita en USEPA 1998c). Sin embargo otros estudios no han encontrado que el  $\text{Cr}(\text{III})$  sea clastogénico incluyendo el  $\text{Cr}_2(\text{SO}_4)_3$  en células FM3A de ratones (Umeda y Nishimura 1979, según se cita en USEPA 1998c) y células de hámsters chinos Don (Ohno 1982, según se cita en USEPA 1998c); y el  $\text{CrCl}_3$  y  $\text{Cr}(\text{NO}_3)_3$  en leucocitos humanos cultivados (Nakamuro 1978, según se cita en USEPA 1998c).

Generalmente los compuestos de cromo (III) son menos tóxicos que los compuestos de  $\text{Cr}(\text{VI})$ , debido a que los compuestos de  $\text{Cr}(\text{III})$  no atraviesan la membrana celular a diferencia de los compuestos de  $\text{Cr}(\text{VI})$  (ATSDR 2000). Sin embargo una vez que los compuestos de  $\text{Cr}(\text{III})$  ingresan a las células, al parecer son más genotóxicos que los compuestos de  $\text{Cr}(\text{VI})$  en objetivos sub-celulares *in vitro*, pero no en sistemas celulares (ATSDR 2000).

### Cromo (VI)

Los compuestos de cromo (VI) resultaron positivos en la mayoría de los ensayos realizados y su genotoxicidad se relacionó con la solubilidad y biodisponibilidad para los sistemas objetivo (ATSDR 2000). El cromo hexavalente se absorbe rápidamente por las células mediante el sistema de transporte del sulfuro y se reduce a la forma trivalente por los sistemas celulares. Se demostró que el cromo hexavalente es genotóxico únicamente en presencia de los agentes de reducción apropiados *in vitro* o en sistemas celulares viables *in vitro* o *in vivo* (USEPA 1998d). También se demostró que el cromo hexavalente es mutágeno en sistemas bacterianos en ausencia de sistemas de activación mamíferos (Venitt y Levy 1974, Nichioka 1975, Nakamuro 1978, Green 1976, Kanematsu 1980, Lofroth y Ames 1978, Newbold 1979, Bonatti 1976 y Fukanaga; 1982 según se cita en USEPA 1998d). Otros estudios indican que los compuestos de cromo (VI) no son mutágenos en presencia de un sistema de activación mamífero (Lofroth 1978, Petrilli y DeFlora 1977, 1978a, 1978b; según se cita en USEPA 1998d). USEPA (1998d) indica que el cromo hexavalente demostró ser mutágeno en sistemas eucarióticos (*Saccharomyces cerevisiae* y *Schizosaccharomyces pombe*, Bonatti 1976, Newbold 1979, Fukanaga 1982; según se cita en USEPA 1998d) y clastógeno en células mamíferas cultivadas (Raffetto 197, Levis y Majone 1979, Umeda y Nishimura 1979, Tsuda y Kat 1977, Newbold 1979, Nakamuro 1978, Stella 1982, Ohno 1982, Gomez-Arroyo 1981, Wild 1978, y Sarto 1982; según se cita en USEPA 1998d).

La exposición oral a compuestos de cromo (VI) no indicó aumento de la incidencia de micronúcleos en eritrocitos policromáticos de ratones (Mirsalis 1996, según se cita en ATSDR 2000) o de síntesis de AND no programada en ratas (Coogan 1991, según se

cita en ATSDR 2000). Sin embargo se observó un aumento significativo de aberraciones cromosómicas en las células de la médula ósea de ratones que se expusieron a trióxido de cromo (IV) por sonda (Sarkar 1993, según se cita en ATSDR 2003). No se encontraron estudios sobre la genotoxicidad de humanos expuestos a Cr(VI) por vía oral (ATSDR 2003).

## Pendiente de la Curva de Factores del Cáncer

### Riesgo de Desarrollar Cáncer a Partir de una Exposición Oral

Actualmente no se dispone de un factor de pendiente oral para el Cr(III) en forma de sales insolubles (USEPA 1998a) y tampoco para el Cr(VI) (USEPA, 1998b).

### Riesgo de desarrollar cáncer a partir de una exposición por inhalación

*Health Canada* (2009) estableció un factor de pendiente de inhalación de  $(47.6 \text{ mg/kg/día})^{-1}$ .

Actualmente no se dispone de un factor de pendiente de inhalación para el Cr(III) en forma de sales insolubles (USEPA 1998a)

Según la ocurrencia de cáncer pulmonar en un estudio ocupacional con seres humanos el riesgo unitario aéreo para el Cr(VI) es  $1.2\text{E-}2 \text{ (}\mu\text{g/m}^3\text{)}^{-1}$  (USEPA 1998b).

La Organización Mundial de la Salud (OMS) dedujo un riesgo unitario en base a estudios entre trabajadores expuestos a cromo (VI) y su susceptibilidad al cáncer pulmonar. No se podría recomendar un nivel de seguridad para el cromo (VI) cuando se asume una relación lineal de dosis-respuesta. La OMS estimó un riesgo de por vida de  $4.0 \times 10^{-2}$  con una concentración en el aire de  $1 \mu\text{g/m}^3$ .

## Resumen

### Cromo total

#### Cr(III)

|                                   |               |                        |             |
|-----------------------------------|---------------|------------------------|-------------|
| DR crónica oral                   | 1.5 mg/kg/día | NOAEL                  | USEPA 1998a |
| CR por inhalación                 | 1.5 mg/kg/día | extrapolación por ruta |             |
| factor de pendiente oral          | no disponible |                        | USEPA 1998a |
| factor de pendiente de inhalación | no disponible |                        | USEPA 1998a |

### Cr(VI)

|                                             |                                       |                        |             |
|---------------------------------------------|---------------------------------------|------------------------|-------------|
| DR crónica oral                             | 3E-3 mg/kg/día                        | NOAEL                  | USEPA 1998b |
| CR por inhalación (a)                       | 8E-6 mg/m <sup>3</sup>                | daño nasal             | USEPA 1998b |
| CR por inhalación (b)                       | 1E-4 mg/m <sup>3</sup>                | efectos en pulmones    | USEPA 1998b |
| DR <sub>i</sub> por inhalación <sup>1</sup> | 2.86E-6 mg/kg/día                     | conversión de unidades |             |
| factor de pendiente oral                    | no disponible                         |                        | USEPA 1998b |
| riesgo unitario por inhalación              | 40 (mg/m <sup>3</sup> ) <sup>-1</sup> | cáncer pulmonar        | OMS 2000    |

Nota: existen dos valores de CR para el Cr(VI); (a) se refiere a vapores y aerosoles de ácido de cromo, (b) se refieren a partículas. La CR para partículas se utilizó en esta evaluación de riesgos.

<sup>1</sup> seleccionado para esta evaluación de riesgos.

<sup>2</sup> se aplicó un factor de corrección de 10X a la DR crónica oral para representar la posible mutagenicidad.
